```

CFx models

Questions/Hypotheses we're interested in: -How does force change in each segment across speed or species? - How does thrust/drag compare across high to low pressure type? -How does thrust/drag in segments compare across pressure type?

Stats analysis completed following the protocol in Zuur et al. Zuur, A. F., Ieno, E. N., Walker, N., Saveliev, A. A. and Smith, G. M. (2009). Mixed effects models and extensions in ecology with R. New York, NY: Springer New York.

build model

Find random term structure

Start with a basic linear model and a basic mixed effects model for comparisons (we believe that individual has to be a random effect).

Hide

```
m2 <- gls(absMeanCFxByMechSidesAvg ~ forceType*pressType*species*segment, data = speciescomp_data_nosides)
```

Hide

```
m3 <- lme(absMeanCFxByMechSidesAvg ~ forceType*pressType*species*segment,  
          random = ~1|individual, data = speciescomp_data_nosides)
```

compare models

Hide

```
anova(m2,m3)
```

Model <int>	df <dbl>	AIC <chr>	BIC <chr>	logLik <chr>	Test <fctr>	L.Ratio <chr>	p-value <chr>
m2	1	57	-7344.703	-7092.578	3729.352		
m3	2	58	-7348.925	-7092.377	3732.463	1 vs 2	6.221797
2 rows							

Do a p-value correction for testing on the boundary

Hide

```
0.5*(1-pchisq(6.221792, 1))
```

```
[1] 0.006309367
```

This p-value is still below our significance threshold, so we accept individual as a random intercept term.

We are data-limited, so take this as our random structure (we don't have enough data to fit random slopes)

Check for heterogeneity

Plot residuals

Hide

```
plot(m3)
```

So, we see there is heteroskedasticity. But where does it come from?

Hide

```
grid.arrange(
  ggplot(speciescomp_data_nosides, aes(x = forceType, y = resid(m3)))
    + geom_boxplot() + papertheme + ggtitle("force type"),

  ggplot(speciescomp_data_nosides, aes(x = pressType, y = resid(m3)))
    + geom_boxplot() + papertheme + ggtitle("pressure type"),

  ggplot(speciescomp_data_nosides, aes(x = species, y = resid(m3)))
    + geom_boxplot() + papertheme + ggtitle("species"),

  ggplot(speciescomp_data_nosides, aes(x = segment, y = resid(m3)))
    + geom_boxplot() + papertheme + ggtitle("segment"),

  ncol=4
)
```

Ok, so it seems like all factors have some level of unequal variances. Segment particularly, and maybe species and pressType.

Hide

```
grid.arrange(
  ggplot(speciescomp_data_nosides, aes(x = segment, y = resid(m3)))
    + geom_boxplot() + papertheme + ggtitle("segment"),

  ggplot(speciescomp_data_nosides, aes(x = segment, y = resid(m3), color = forceType))
    + geom_boxplot() + papertheme + ggtitle("force type"),

  ggplot(speciescomp_data_nosides, aes(x = segment, y = resid(m3), color = pressType))
    + geom_boxplot() + papertheme + ggtitle("pressure type"),

  ggplot(speciescomp_data_nosides, aes(x = segment, y = resid(m3), color = species))
    + geom_boxplot() +papertheme + ggtitle("species"),

  ncol=2
)
```

The patterns vs segment didn't change much when broken up by the other factors. Trout seems to consistently have more variance than bluegill. Pressure type doesn't have a consistent pattern - lo and hi both have larger variances depending on the segment. Force type is pretty equal except in the last segment.

Hide

```

grid.arrange(
  ggplot(speciescomp_data_nosides, aes(x = species, y = resid(m3)))
    + geom_boxplot() + papertheme + ggtitle("species"),

  ggplot(speciescomp_data_nosides, aes(x = species, y = resid(m3), color = forceType))
    + geom_boxplot() + papertheme + ggtitle("force type"),

  ggplot(speciescomp_data_nosides, aes(x = species, y = resid(m3), color = pressType))
    + geom_boxplot() + papertheme + ggtitle("pressure type"),

  ggplot(speciescomp_data_nosides, aes(x = species, y = resid(m3), color = segment))
    + geom_boxplot() + papertheme + ggtitle("segment"),

  ncol=2
)

```

As above, see that trout variance is larger vs segments, but hard to say what the difference is between species based on pressType or forceType.

Find variance structure

Look for what could be causing issues with residuals by marking them up with color.

Hide

```
grid.arrange(
  ggplot(speciescomp_data_nosides, aes(x = fitted(m3), y = residuals(m3), color = segment))
    + geom_point(alpha = 0.4) + papertheme + ggtitle("segment"),

  ggplot(speciescomp_data_nosides, aes(x = fitted(m3), y = residuals(m3), color = species))
    + geom_point(alpha = 0.4) + papertheme + ggtitle("species"),

  ggplot(speciescomp_data_nosides, aes(x = fitted(m3), y = residuals(m3), color = forceType))
    + geom_point(alpha = 0.4) + papertheme + ggtitle("forceType"),

  ggplot(speciescomp_data_nosides, aes(x = fitted(m3), y = residuals(m3), color = pressType))
    + geom_point(alpha = 0.4) + papertheme + ggtitle("pressType"),

  ncol = 2
)
```

Segment and pressType are probably the issue (the really big values all from segment 1 and 7, hi pressure), but trout does have some larger residuals than bluegill

Let's try some variance structures out.

Note: `varIdent(form = ~ 1|forceTypepressTypespeciessegment)` nor `varIdent(form = ~ 1|pressTypespeciessegment)` nor `varIdent(form = ~ 1|pressTypesegment)`

converge. So, let's do what we can...

Let's do groups of 2 and then single.

Hide

```

vfsc1 <- varIdent(form = ~ 1|species*segment)
vfsc2 <- varIdent(form = ~ 1|pressType*species)
vfsc3 <- varIdent(form = ~ 1|segment)
vfsc4 <- varIdent(form = ~ 1|pressType)
vfsc5 <- varIdent(form = ~ 1|species)

```

Set up REML models with different variance structures.

Hide

```

m3.1 <- lme(absMeanCFxByMechSidesAvg ~ forceType*pressType*species*segment,
            random = ~1|individual,
            data = speciescomp_data_nosides,
            weights = vfsc1)
m3.2 <- lme(absMeanCFxByMechSidesAvg ~ forceType*pressType*species*segment,
            random = ~1|individual,
            data = speciescomp_data_nosides,
            weights = vfsc2)
m3.3 <- lme(absMeanCFxByMechSidesAvg ~ forceType*pressType*species*segment,
            random = ~1|individual,
            data = speciescomp_data_nosides,
            weights = vfsc3)
m3.4 <- lme(absMeanCFxByMechSidesAvg ~ forceType*pressType*species*segment,
            random = ~1|individual,
            data = speciescomp_data_nosides,
            weights = vfsc4)
m3.5 <- lme(absMeanCFxByMechSidesAvg ~ forceType*pressType*species*segment,
            random = ~1|individual,
            data = speciescomp_data_nosides,
            weights = vfsc5)

```

Compare using AIC

Hide

```
AIC(m3, m3.1, m3.2, m3.3, m3.4, m3.5)
```

	df <dbl>	AIC <dbl>
m3	58	-7348.925
m3.1	71	-7695.483
m3.2	61	-7471.708
m3.3	64	-7613.016
m3.4	59	-7365.740
m3.5	59	-7463.706
6 rows		

The m3.1 model wins.

Check residuals.

Hide

```
plot(m3.1)
```

Better than model without the unequal variance specification.

Look for optimal fixed structure

Start by finding out if highest-order interaction term is significant.

Hide

```
anova(m3.1)
```

	num...	denDF	F-value	p-value
	<int>	<dbl>	<chr>	<chr>

forceType:pressType:segment	1472.9961	6	< 2.2e-16	***
forceType:species:segment	45.9720	6	2.999e-08	***
pressType:species:segment	29.2642	6	5.422e-05	***
forceType:pressType:species:segment	24.7870	6	0.0003739	***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Again, 4-way interaction is highly significant, so we keep all the terms.

Final descriptive CFx model (species comparison)

Force magnitude depends on force type, pressure type, species, and segment when the effect of individuals is controlled for, and we allow for differing variances across segments and species.

Hide

```
speciescomp_CFx_descriptive <- lme(absMeanCFxByMechSidesAvg ~ forceType*pressType*species*segment,
                                random = ~1|individual,
                                data = speciescomp_data_nosides,
                                weights = varIdent(form = ~ 1|species*segment))
```

One last check - qq plot

Hide

```
qqnorm(speciescomp_CFx_descriptive)
```

Ok, still not fabulous, but there may be enough data to not worry about non-normality.

Hide

```
summary(speciescomp_CFx_descriptive)
```

CFx (total) models

build model

Find random effects

Assume individual is a random effect, but let's demonstrate it.

Hide

```
testCFxBgTr_0 <- gls(meanCFxInSegmSidesAvg ~ species + segment + species:segment, data = species
comp_data_nosides)
testCFxBgTr_1 <- lme(meanCFxInSegmSidesAvg ~ species + segment + species:segment,
random = ~1|individual, data = speciescomp_data_nosides)
```

compare models

Hide

```
anova(testCFxBgTr_0, testCFxBgTr_1)
```

	Model	df	AIC	BIC	logLik	Test	L.Ratio	p-value
	<int>	<dbl>	<chr>	<chr>	<chr>	<fctr>	<chr>	<chr>
testCFxBgTr_0	1	15	-7146.537	-7079.199	3588.268			
testCFxBgTr_1	2	16	-7150.782	-7078.955	3591.391	1 vs 2	6.24547	0.0125

2 rows

Do a p-value correction for testing on the boundary

Hide

```
0.5*(1-pchisq(6.24547, 1))
```

```
[1] 0.006225567
```

This p-value is still below our significance threshold, so we accept individual as a random intercept term.

We are data-limited, so take this as our random structure (we don't have enough data to fit random slopes)

Check for heterogeneity

Plot residuals

Hide

```
plot(testCFxBgTr_1)
```

Possibly some heterogeneity. Hard to tell if other issues are in play too. Let's see if there is a cause for heterogeneity.

Hide

```
grid.arrange(  
  ggplot(speciescomp_data_nosides, aes(x = species, y = resid(testCFxBgTr_1)))  
    + geom_boxplot() + papertheme + ggtitle("species"),  
  
  ggplot(speciescomp_data_nosides, aes(x = segment, y = resid(testCFxBgTr_1)))  
    + geom_boxplot() + papertheme + ggtitle("segment"),  
  
  ncol=2  
)
```

Variances are unequal across segments and species

Hide

```
grid.arrange(
  ggplot(speciescomp_data_nosides, aes(x = fitted(testCFxBgTr_1), y = residuals(testCFxBgTr_1),
  color = segment))
  + geom_point(alpha = 0.4) + papertheme + ggtitle("segment"),

  ggplot(speciescomp_data_nosides, aes(x = fitted(testCFxBgTr_1), y = residuals(testCFxBgTr_1),
  color = species))
  + geom_point(alpha = 0.4) + papertheme + ggtitle("species"),

  ncol = 2
)
```

Definitely issues due to both segments and species.

Let's see if adding a variance structure helps.

Hide

```
testCFxBgTr_1a <- lme(meanCFxInSegmSidesAvg ~ species + segment + species:segment,
                      weights = varIdent(form = ~1|species),

CFy models

We don't care if force is going left or right, just the magnitude. So let's take the absolute value of CFy.

Hide

```

bluegill_data_nosides$absMeanCFyInSegmSidesAvg <- abs(bluegill_data_nosides$meanCFyInSegmSidesAvg)
speciescomp_data_nosides$absMeanCFyInSegmSidesAvg <- abs(speciescomp_data_nosides$meanCFyInSegmSidesAvg)

```

build model

Find random effects

Assume individual is a random effect, but let's demonstrate it.

Hide

```
testCFyBgTr_0 <- gls(absMeanCFyInSegmSidesAvg ~ species + segment + species:segment, data = speciescomp_data_nosides)
testCFyBgTr_1 <- lme(absMeanCFyInSegmSidesAvg ~ species + segment + species:segment,
                    random = ~1|individual, data = speciescomp_data_nosides)
```

compare models

Hide

```
anova(testCFyBgTr_0, testCFyBgTr_1)
```

	Mo... <int>	df <dbl>	AIC <chr>	BIC <chr>	logLik <chr>	Test <fctr>	L.Ratio <chr>	p-value <chr>
testCFyBgTr_0	1	15	-4660.817	-4593.479	2345.409			
testCFyBgTr_1	2	16	-4811.128	-4739.301	2421.564	1 vs 2	152.3107	<.0001

2 rows

Do a p-value correction for testing on the boundary

Hide

```
0.5*(1-pchisq(153.3107, 1))
```

```
[1] 0
```

This p-value is still below our significance threshold, so we accept individual as a random intercept term.

We are data-limited, so take this as our random structure (we don't have enough data to fit random slopes)

Check for heterogeneity

Plot residuals

Hide

```
plot(testCFyBgTr_1)
```

Really bizarre. For sure some heterogeneity. Hard to tell if other issues are in play too. Let's see if there is a cause for heterogeneity.

Hide

```
grid.arrange(  
  ggplot(speciescomp_data_nosides, aes(x = species, y = resid(testCFyBgTr_1)))  
    + geom_boxplot() + papertheme + ggtitle("species"),  
  
  ggplot(speciescomp_data_nosides, aes(x = segment, y = resid(testCFyBgTr_1)))  
    + geom_boxplot() + papertheme + ggtitle("segment"),  
  
  ncol=2  
)
```

Variances are unequal across segments and species

Hide

```

grid.arrange(
  ggplot(speciescomp_data_nosides, aes(x = fitted(testCFyBgTr_1), y = residuals(testCFyBgTr_1),
  color = segment))
  + geom_point(alpha = 0.4) + papertheme + ggtitle("segment"),

  ggplot(speciescomp_data_nosides, aes(x = fitted(testCFyBgTr_1), y = residuals(testCFyBgTr_1),
  color = species))
  + geom_point(alpha = 0.4) + papertheme + ggtitle("species"),

  ncol = 2
)

```

Definitely issues due to both segments and species.

Let's see if adding a variance structure helps. Note that `varIdent(form = ~1|species*segment)` does not converge.

Hide

```
testCFyBgTr_1a <- lme(absMeanCFyInSegmSidesAvg ~ species + segment + species:segment,
                      weights = varIdent(form = ~1|species),
                      random = ~1|individual, data = speciescomp_data_nosides)
testCFyBgTr_1b <- lme(absMeanCFyInSegmSidesAvg ~ species + segment + species:segment,
                      weights = varIdent(form = ~1|segment),
                      random = ~1|individual, data = speciescomp_data_nosides)
```

Compare models

Hide

```
AIC(testCFyBgTr_1, testCFyBgTr_1a, testCFyBgTr_1b)
```

	df	AIC
	<dbl>	<dbl>
testCFyBgTr_1	16	-4811.128
testCFyBgTr_1a	17	-5069.278
testCFyBgTr_1b	22	-5236.370

3 rows

Model with the variance allowed to vary across segments is best by AIC score - HUGE improvement.

So, look at residuals.

Hide

```
plot(testCFyBgTr_1b)
```

Better. Still some patchiness - likely because our data is sparse. Vertical spread is much improved.

Check fixed effects structure

Hide

```
anova(testCFyBgTr_1b)
```

	numDF <int>	denDF <dbl>	F-value <chr>	p-value <chr>
(Intercept)	1	652	1067.9798	<.0001
species	1	6	3.0050	0.1337
segment	6	652	635.9902	<.0001
species:segment	6	652	5.7877	<.0001

4 rows

The interaction term is highly significant - so we need all the terms in our model.

Final bg vs tr CFy model

Hide

```
